## IN THE CLAIMS

Please amend the claims as follows:

1. (currently amended) A method for reducing idle-mode power dissipation in a communication device during absence of off site power, comprising:  
determining whether an active radio frequency ("RF") communication channel is present at a network connection;  
scanning a plurality of possible RF channels using a processor having RF circuitry to detect whether an RF channel is present that can be made active;  
placing ~~at least one portion of the communication device~~ the processor into a sleep mode if an active RF channel or an RF channel that can be made active is not detected;  
starting a timer set for a predetermined period if an active channel or one of the plurality of possible RF channels is not detected; and  
awakening the ~~at least one portion~~ processor from sleep mode when the predetermined period has elapsed.

2. (original) The method of claim 1 further comprising detecting the restoration of offsite power while the timer is counting down the predetermined period and awakening the at least one portion from sleep mode.

3. (canceled)

4. (currently amended) A method for reducing idle-mode power dissipation in a communication device during absence of off site power, comprising:  
determining whether an active radio frequency ("RF") communication channel is present at a network connection;  
scanning a plurality of possible RF channels to detect whether an RF channel is present that can be made active;  
placing at least one portion of the communication device into a sleep mode if an active RF channel or an RF channel that can be made active is not detected;  
starting a timer set for a predetermined period if an active channel or one of the plurality of possible RF channels is not detected; and  
awakening the at least one portion from sleep mode when the predetermined period has elapsed;

~~The method of claim 3 wherein the at least one portion put into sleep mode includes~~ main processor circuitry includes and radio frequency communication circuitry.

5. (original) A method for reducing idle-mode power dissipation in a communication device during absence of off site power, comprising:  
determining whether an active RF communication channel is present at a network connection of the communication device;  
scanning a plurality of possible RF channels to detect whether an RF channel is present that can be made active;

placing at least one portion of the communication device into sleep mode if an active RF channel or an RF channel that can be made active is not detected;  
determining whether RF energy is present at the network connection using an RF energy detecting means;  
awakening the at least one portion from sleep mode when RF energy is detected by the RF energy detecting means; and  
scanning the plurality of possible RF channels to detect whether an RF channel is present that can be made active after awakening following detection of the presence of RF energy;  
wherein the at least one portion put into sleep mode includes main processor circuitry and radio frequency communication circuitry.

6. (original) The method of claim 5 further comprising:  
starting a timer set for a predetermined period if one of the plurality of possible RF channels is not detected following detection of the presence of RF energy;  
placing the at least one portion of the communication device into sleep mode if an RF channel that can be made active is not detected following starting of the timer; and  
awakening the at least one portion from sleep mode when the predetermined period has elapsed.

7. (original) The method of claim 5 further comprising determining whether offsite power has been restored and awakening the at least one portion from sleep mode upon restoration of off site power.

8. (currently amended) A system for reducing power consumption in a communication device having a communication network connection and using a battery backup UPS during a loss of offsite power, comprising:  
a controller means coupled to the UPS for controlling operation of the UPS;  
a processor means for determining whether to reduce power consumption of the communication device, said processor means being coupled to the controller via a communication means; and  
a switching means for placing ~~at least one circuitry portion of the communication device in the processor means into~~ a sleep mode by interrupting power from the UPS to ~~said at least one portion the processor means~~ in response to a control signal from the controller, wherein the control signal is initiated by the processor means upon determining that power consumption of the communication device should be reduced.

9. (original) The system of claim 8 further comprising an RF detecting means for determining whether RF energy is present at the network connection.

10. (currently amended) The system of claim 9 wherein the RF detecting means can detect the presence of RF energy while the ~~at least one circuitry portion processor~~ is in sleep mode.

DOCKET 8151

11. (currently amended) The system of claim 8 wherein the processor means includes RF communication circuitry.

12. (currently amended) The system of claim 9 wherein the RF detecting means and the processor means share passive RF components.

13. (original) The system of claim 8 wherein the UPS includes the switching means.

14. (original) The system of claim 8 wherein the controller includes computing means for storing and running executable instruction code.

15. (original) The system of claim 14 wherein the instruction code includes a timer for maintaining the at least one circuitry portion in a sleep mode for a predetermined period of time.

16. (canceled)

17. (original) The system of claim 8 wherein the controller includes a monitoring means coupled to the UPS for sensing when off site AC power is present at the UPS.

18. (original) The system of claim 8 wherein the processor means includes computing means for storing and running executable instruction code.

19. (currently amended) The system of claim 18 wherein the executable instruction code includes a method for making the determination as to whether to place the ~~at least one circuitry portion~~ processor means in sleep mode on the presence of an active communication channel.

20. (currently amended) The system of claim 14 wherein the instruction code includes a method for awakening the ~~at least one circuitry portion~~ processor means from sleep mode upon the occurrence of a predetermined factor.

21. (original) The system of claim 20 wherein the predetermined factor is the elapsing of a predetermined period of time measured by a timer.

22. (original) The system of claim 20 wherein the predetermined factor includes the detection of the presence of RF energy at the network connection.
